sklearn.svm.SVC

class sklearn.svm.**SVC**(*, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None) [source]

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using <u>LinearSVC</u> or <u>SGDClassifier</u> instead, possibly after a <u>Nystroem</u> transformer or other <u>Kernel Approximation</u>.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how gamma, coef0 and degree affect each other, see the corresponding section in the narrative documentation: Kernel functions.

Read more in the User Guide.

Parameters:

C: float, default=1.0

Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared I2 penalty.

kernel: {'linear', 'poly', 'rbf', 'sigmoid', 'precomputed'} or callable, default='rbf'

Specifies the kernel type to be used in the algorithm. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix from data matrices; that matrix should be an array of shape (n_samples, n_samples). For an intuitive visualization of different kernel types see <u>Plot classification boundaries with different SVM Kernels</u>.

degree: int, default=3

Degree of the polynomial kernel function ('poly'). Must be non-negative. Ignored by all other kernels.

gamma: {'scale', 'auto'} or float, default='scale'

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

- if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
- if 'auto', uses 1 / n_features
- if float, must be non-negative.

Changed in version 0.22: The default value of gamma changed from 'auto' to 'scale'.

coef0: float, default=0.0

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

shrinking: bool, default=True

Whether to use the shrinking heuristic. See the User Guide.

probability: bool, default=False

Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the <u>User Guide</u>.

tol: float, default=1e-3

Tolerance for stopping criterion.

cache_size: float, default=200

Specify the size of the kernel cache (in MB).

class_weight : dict or 'balanced', default=None

Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_s amples / $(n_c$ lasses * n_s .bincount(y)).

verbose: bool, default=False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, default=-1

Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape : {'ovo', 'ovr'}, default='ovr'

Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2). However, note that internally, one-vs-one ('ovo') is always used as a multi-class strategy to train models; an ovr matrix is only constructed from the ovo matrix. The parameter is ignored for binary classification.

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

break_ties : bool, default=False

If true, decision_function_shape='ovr', and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

random_state : int, RandomState instance or None, default=None

Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when probability is False. Pass an int for reproducible output across multiple function calls. See <u>Glossary</u>.

Attributes:

class_weight_: ndarray of shape (n_classes,)

Multipliers of parameter C for each class. Computed based on the class_weight parameter.

classes_: ndarray of shape (n_classes,)

The classes labels.

coef_ : ndarray of shape (n_classes * (n_classes - 1) / 2, n_features)

Weights assigned to the features when kernel="linear".

dual_coef_: ndarray of shape (n_classes -1, n_SV)

Dual coefficients of the support vector in the decision function (see <u>Mathematical formulation</u>), multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the <u>multi-class section of the User Guide</u> for details.

fit_status_: int

0 if correctly fitted, 1 otherwise (will raise warning)

intercept_: ndarray of shape (n_classes * (n_classes - 1) / 2,)

Constants in decision function.

n_features_in_: int

Number of features seen during fit.

New in version 0.24.

feature_names_in_: ndarray of shape (n_features_in_,)

Names of features seen during fit. Defined only when X has feature names that are all strings.

New in version 1.0.

n_iter_: ndarray of shape (n_classes * (n_classes - 1) // 2,)

Number of iterations run by the optimization routine to fit the model. The shape of this attribute depends on the number of models optimized which in turn depends on the number of classes.

New in version 1.1.

support_: ndarray of shape (n_SV)

Indices of support vectors.

support_vectors_: ndarray of shape (n_SV, n_features)

Support vectors. An empty array if kernel is precomputed.

n_support_: ndarray of shape (n_classes,), dtype=int32

Number of support vectors for each class.

probA : ndarray of shape (n_classes * (n_classes - 1) / 2)

Parameter learned in Platt scaling when probability=True.

probB_ : ndarray of shape (n_classes * (n_classes - 1) / 2)

Parameter learned in Platt scaling when probability=True.

shape_fit_: tuple of int of shape (n_dimensions_of_X,)

Array dimensions of training vector X.

Methods

Evaluate the decision function for the samples in X.
Fit the SVM model according to the given training data.
Get metadata routing of this object.
Get parameters for this estimator.
Perform classification on samples in X.
Compute log probabilities of possible outcomes for samples in X.
Compute probabilities of possible outcomes for samples in X.
Return the mean accuracy on the given test data and labels.
Request metadata passed to the fit method.
Set the parameters of this estimator.
Request metadata passed to the score method.

property coef_

Weights assigned to the features when kernel="linear".

Returns:

ndarray of shape (n_features, n_classes)

decision_function(X) [source]

Evaluate the decision function for the samples in X.

Parameters:

X : array-like of shape (n_samples, n_features)

The input samples.

Returns:

X: ndarray of shape (n_samples, n_classes * (n_classes-1) / 2)

Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).

Notes

If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

 $fit(X, y, sample_weight=None)$

[source]

Fit the SVM model according to the given training data.

Parameters:

X: {array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples)

Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y: array-like of shape (n_samples,)

Target values (class labels in classification, real numbers in regression).

sample_weight : array-like of shape (n_samples,), default=None

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns:

self : object

Fitted estimator.

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_metadata_routing()

[source]

Get metadata routing of this object.

Please check <u>User Guide</u> on how the routing mechanism works.

Returns:

routing: MetadataRequest

A <u>MetadataRequest</u> encapsulating routing information.

get_params(deep=True)

[source]

Get parameters for this estimator.

Parameters:

deep: bool, default=True

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns:

params: dict

Parameter names mapped to their values.

property n_support_

Number of support vectors for each class.

predict(X)

[source]

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters:

X: {array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples_test, n_samples_train)

For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns:

y_pred : ndarray of shape (n_samples,)

Class labels for samples in X.

predict_log_proba(X)

[source]

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters:

X : array-like of shape (n_samples, n_features) or (n_samples_test, n_samples_train)

For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns:

T: ndarray of shape (n_samples, n_classes)

Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute <u>classes</u>.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

predict_proba(X)
[source]

Compute probabilities of possible outcomes for samples in X.

The model needs to have probability information computed at training time: fit with attribute probability set to True.

Parameters:

X : array-like of shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns:

T: ndarray of shape (n_samples, n_classes)

Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute <u>classes</u>.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

property probA_

Parameter learned in Platt scaling when probability=True.

Returns:

ndarray of shape (n classes * (n classes - 1) / 2)

property probB

Parameter learned in Platt scaling when probability=True.

Returns

ndarray of shape (n_classes * (n_classes - 1) / 2)

score(X, y, sample_weight=None)

[source]

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters:

X: array-like of shape (n_samples, n_features)

Test samples.

y: array-like of shape (n_samples,) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like of shape (n_samples,), default=None

Sample weights.

Returns:

score: float

Mean accuracy of self.predict(X) w.r.t. y.

set_fit_request(*, sample_weight: <u>Union[bool</u>, <u>None</u>, <u>str</u>] = '\$UNCHANGED\$') → <u>SVC</u>

[source]

Request metadata passed to the fit method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- True: metadata is requested, and passed to fit if provided. The request is ignored if metadata is not provided.
- False: metadata is not requested and the meta-estimator will not pass it to fit.
- None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

New in version 1.3.

Note: This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a **Pipeline**. Otherwise it has no effect.

Parameters:

sample_weight: str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED

Metadata routing for sample weight parameter in fit.

Returns:

self: object

The updated object.

set_params(**params)

[source]

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as <u>Pipeline</u>). The latter have parameters of the form component>__<parameter> so that it's possible to update each component of a nested object.

Parameters:

**params : dict

Estimator parameters.

Returns:

self: estimator instance

Estimator instance.

 $set_score_request(*, sample_weight: \underline{Union[bool}, \underline{None}, \underline{str}] = '\$UNCHANGED$') \rightarrow \underline{SVC}$

[source]

Request metadata passed to the score method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- True: metadata is requested, and passed to score if provided. The request is ignored if metadata is not provided.
- False: metadata is not requested and the meta-estimator will not pass it to score.
- None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

New in version 1.3.

Note: This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters:

sample_weight: str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED

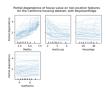

Metadata routing for sample_weight parameter in score.

Returns:

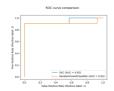

self : object

The updated object.
